

THE ENDOTHECIUM IN *INULA* L., AND ITS ALLIED GENERA (INULEAE – COMPOSITAE) FROM PAKISTAN AND KASHMIR

RUBINA ABID AND MOHAMMAD QAISER

Department of Botany,
University of Karachi, Karachi, Pakistan.

Abstract

The endothecium in 22 species of *Inula* L., and its allied genera (*Pentanema* Cass., *Duhaldea* DC., *Dittrichia* Greuter and *Iphiona* Cass.) was examined from Pakistan and Kashmir by light microscopy. Three types of endothelial tissues i.e., polar, radial and transitional are recognized. In the genus *Inula* radial and transitional endothecium are present whereas, in the genera *Pentanema*, *Dittrichia* and *Iphiona* is radial while the genus *Duhaldea* is characterized by polar endothecium.

Introduction

Endothecium is usually termed for layers of anther wall between fibrous layer and the sporogenous tissues or all layers of anther wall excluding epidermis (Eames, 1961). The endothecium forming the distinct ribs or bars are differentiated on the anticinal, pericinal and transverse walls of the cell (Esau, 1977). According to these configuration of ribs, there are three main types of endothelial tissues (Dormer, 1962; Nordenstam, 1976, 1978; Wetter, 1983). When the ribs are restricted to the transverse or horizontal walls, endothelial tissues are polarized. When ribs are all around, the configuration is said to be radial. But when the endothelial cells are uniformly thickened or in undistinguished manner with no distinct ribs these are said to be transitional endothelial tissues. The exact function of these thickening is ambiguous but most probably they act by creating tension in the maturing anthers and help in pollen dispersal (Esau, 1977; Endress, 1994; Tebbitt & Maciver, 1999). From time to time many workers utilized endothelial tissues with taxonomic interpretations in various taxa such as in Asteraceae (Dormer, 1962; Vincent & Getliffe, 1988; Anderberg, 1991), Apiaceae (Arora & Tiagi, 1977), Onagraceae (Eyde, 1977), Araceae (French, 1985), Iridaceae (Manning & Goldblatt, 1990), Orchidaceae (Freudenstein, 1991), Leguminosae (Manning & Stirton, 1994) and Begoniaceae (Tebbit & Maciver, 1999).

There are various reports on endothelial tissues of various taxa but there are no reports on *Inula* and its related genera from the area under consideration. The present report describes the endothelial type of *Inula* L., *Pentanema* Cass., *Duhaldea* DC., *Dittrichia* Greuter and *Iphiona* Cass., from Pakistan and Kashmir.

Materials and Methods

Twenty two species belonging to the genera *Inula* L., *Pentanema* Cass., *Duhaldea* DC., *Dittrichia* Greuter and *Iphiona* Cass., were investigated for endothelial tissues. A list of specimens investigated is given in Table 1. Syngenesious anthers were cleared by heating in 50% lactic acid. The cleared anthers were dissected and mounted in lactic acid. The endothelial thickening was observed from the abaxial surface of the anther under compound microscope (Nikon Type – 102).

Result and Discussion

According to the endothecium thickening, all the studied taxa are placed in three different categories i.e., polar, radial and transitional endothelial tissues (Dormer, 1962; Nordenstam, 1976, 1978). Anderberg (1991) described the radial endothecium in *Inula* L., but the present studies reveal that in *Inula* both radial and transitional types are present (Table 1). In *Inula koelzii* Dawar & Qaiser, *I. racemosa* Hook. f., *I. royleana* DC., and *I. stewartii* Dawar & Qaiser, endothelial thickenings are uniform and indistinguishable i.e. transitional type (Fig. 1A, B). Whereas, in the remaining species of *Inula*, radial endothelial tissues are observed (Fig. 1C-G). It is also interesting to note that the group of above four species of *Inula* is also distinguished from remaining species due to the presence of upper sessile and semiamplexicaul leaves and lower ones are attenuate in a long winged petiole, cypselas 3-4 mm long ± glabrous and 16-24 -ribbed. Whereas, in remaining species leaves are not winged petiolate, cypselas 8-12- ribbed and hairy. In *Duhaldea*, endothelial tissues are polarized (Fig. 2C-F), while in *Pentanema* (Fig. 1H, I; 2A, B), *Dittrichia* (Fig. 2G) and *Iphiona* (Fig. 2H, I) radial type is found. However, our findings in *Dittrichia* and *Iphiona* are not in accordance to those of Anderberg (1991) where he described polar endothelial tissues in both the genera.

Acknowledgement

We are grateful to the Directors/Curators of E, K, KUH, LIV and RAW for providing the herbarium material on loan.
