

SURVEY OF FRESHWATER ALGAE FROM KARACHI, PAKISTAN

R. ALIYA¹, A. ZARINA² AND MUSTAFA SHAMEEL¹

¹Department of Botany, University of Karachi, Karachi-75270, Pakistan

²Department of Botany, Federal Urdu University of Arts, Science & Technology,
Gulshan-e-Iqbal Campus, Karachi-75300, Pakistan.

Abstract

Altogether 214 species of algae belonging to 86 genera of 33 families, 15 orders, 10 classes and 6 phyla were collected from various freshwater habitats in three towns of Karachi City during May 2004 and September 2005. Among various phyla, Cyanophycota was represented by 82 species (38.32%), Volvophycota by 78 species (36.45%), Euglenophycota by 4 species (1.87%), Chrysophycota by 2 species (0.93%), Bacillarophycota by 38 species (17.76%) and Chlorophycota by 10 species (4.67%). Members of the phyla Cyanophycota and Volvophycota were most prevalent (74.8%) and those of Euglenophycota and Chrysophycota poorly represented (2.8%).

Introduction

Karachi, the largest city of Pakistan is spread over a vast area of 3,530 km² and includes a variety of ponds, streams, water falls, artificial and natural water reservoirs and two small ephemeral rivers with their branchlets, which inhabit several groups of freshwater algae. Only a few studies have been carried out in the past on different groups of these algae, either from a point of view of their habitats and general occurrence (Parvaiz & Ahmed, 1981; Shameel & Butt, 1984; Aisha & Hasni, 1991; Aisha & Zahid, 1991; Leghari *et al.*, 2002) or from taxonomic viewpoint (Salim, 1954; Aizaz & Farooqui, 1972; Farzana & Nizamuddin, 1979; Ahmed *et al.*, 1983). Recently, a study was made on the occurrence of algae within Karachi University Campus (Mehwish & Aliya, 2005). Thus the available information about the algal flora of this city was not sufficient. Therefore, a large survey was initiated in May 2004 to collect and identify the freshwater algae from different areas of Karachi.

Materials and Methods

Specimens were collected from various freshwater habitats in three towns (Saddar, Jamshaid and Gulshan-e-Iqbal) of Karachi City during May 2004 and September 2005. They were brought to the laboratory and preserved in 3% formaline solution. The specimens were mounted on glycerin and semi-permanent slides were prepared by sealing the cover-slip with nail polish. They were examined under binocular light microscope and taxonomically determined with the help of authentic literature (Desikachary, 1959; Krieger & Gerloff, 1962, 1965, 1969; Prescott, 1962; Starmach, 1964, 1966; Taft & Taft, 1971; Tiwari, 1975; John *et al.*, 2002; Wehr & Sheath, 2003).

Results and Discussion

The collected specimens of freshwater algae were investigated under microscope and identified up to species level. On the basis of their morphological and cytological characteristics 214 species belonging to 86 genera of 33 families, 15 orders, 10 classes and 6 phyla were observed in three towns of Karachi City (Table 1). They have been systematically arranged according to the recently proposed classification (Shameel, 2001, 2008), therefore the new taxonomic nomenclature has been used here. The phylum Cyanophycota was found to be represented by 82 species (38.32%), Volvophycota by 78 species (36.45%), Euglenophycota by 4 species (1.87%), Chrysophycota by 2 species (0.93%), Bacillarophycota by 38 species (17.76%) and Chlorophycota by 10 species (4.67%). Members of the phyla Cyanophycota and Volvophycota were most prevalent (74.8%) and those of Euglenophycota and Chrysophycota poorly represented (2.8%). No member of the phyla Charophycota and Vaucherophycota was found to occur. These results are nearly similar with the observations made by Leghari *et al.*, (1999) at the water reservoir of Chotiari (Sanghar District, near Karachi), where 157 species of freshwater algae were recorded. Among them, 65.36% species belonged to the phyla Cyanophycota and Volvophycota. Members of the phylum Bacillarophycota were 17.5%, which is almost equal to our observation.

The phylum Cyanophycota exhibited largest diversity with 82 species. Our results are also comparable with the observations made by Leghari *et al.*, (2003) at the water reservoirs of Wah Garden (district Attock), where species of the phyla Cyanophycota and Volvophycota were dominant during summer seasons because physico-chemical factors such as high temperature, alkaline pH, high light intensity and stagnant water conditions were suitable for their excessive growth.

Gulshan-e-Iqbal Town exhibited largest number of algal flora than other two towns, although these towns included the water reservoirs of Hill Park and Askari Park. The reason may be that the large area of Karachi University Campus is also included in Gulshan-e-Iqbal Town, where several water ponds, ditches and water channels are situated in educational departments showing a luxuriant growth of algae, as has been previously observed by Mehwish & Aliya (2005). The smallest number of algal species were observed in Saddar Town, where the collections were mainly obtained from Zoological Garden. The water at most of the pools and ditches in the garden is highly polluted due to waste thrown by children and visitors, which adversely affects the growth of algae.

It was observed that the growth of microscopic species was abundant, especially in the planktonic state. The differences in the percentage of species in various towns is due to different environmental conditions like temperature, pH and growth conditions as was observed in a variety of water pools at Rawal Dam (Leghari *et al.*, 2005). Species of the phylum Chrysophycota were found in smallest proportion (0.93%), as high water temperature (25-29°C) does not appear to be suitable for their growth. Similar observations were made in the previous studies at Karachi (Leghari *et al.*, 2002; Mehwish & Aliya, 2005).
